

# ***TopoClusters for UE studies using 900 GeV data***

***S.Chekanov, J.Proudfoot, R.Yoshida, J.Zhang***  
(HEP division, ANL, USA)

***C.Bertella, P.Francavilla, C.Roda***  
(Universita' e I.N.F.N. Pisa, Italy)

***April 7, 2010***

***UE meeting, Status report***

# Goals

## ◆ Use TopoClusters for the UE studies

- Systematically completely independent of tracking
- Look at a complete final state (charged & neutral particles)
- More relevant for future jet-based studies

## ◆ Understand relationship between a particle and a TopoCluster

## ◆ Understand energy scale, resolution, unfolding procedure & systematic

## ◆ As a side study, to check what exactly goes into the jet constituents

Picture from P.Loch's talk

## Expected features:

- threshold effect ( for TopoClusters with energy  $\sim 1$  GeV,  $\langle E/p \rangle \sim 0.3$ )
- energy scale uncertainties
- magnetic field distorts the initial direction of charged particles entering the calorimeter
- large resolution (picking highest- $p_T$  cluster does not always means going to a large energy scale)
- particles with large  $p_T$  inside jets can be represented by fewer clusters (overlap effects)
  - can lead to a significant unfolding correction at large  $p_T$

## Event selection and observables

- ◆ Good runs Solenoid=ON, Toroid=ON
  - 141565, 141707, 141746, 141748, 141811, 142166, 142191, 142193, 142195, 142383
- ◆ Monte Carlo sample: ATLAS-GEO-08-00-02 (r1051)
- ◆ L1\_MBTS\_1 trigger
- ◆ At least 3 tracks for the primary vertex
- ◆ Calibrated TopoClusters

Analysis is done using ESD's  
(ESD->Ntuples->Histograms) at ANL Tier3

### UE measurements:

Repeat the tracking measurements presented in  
ATL-COM-PHYS-2010-164 and ATL-COM-PHYS-2010-164

- ◆ Select on the highest pT particle (cluster)
- ◆ Use it as an energy scale
- ◆ Calculate difference in azimuthal angle between particle and any other particle in event
- ◆ Repeat the same for different pT's of the leading cluster
- ◆ Look at different regions (toward, transverse, away) and
  - $\langle p_T \rangle$  as a function of  $p_T(\text{lead})$
  - $\langle p_T \rangle$  as function of  $N(\text{clusters})$
  - Same for densities and energy flows

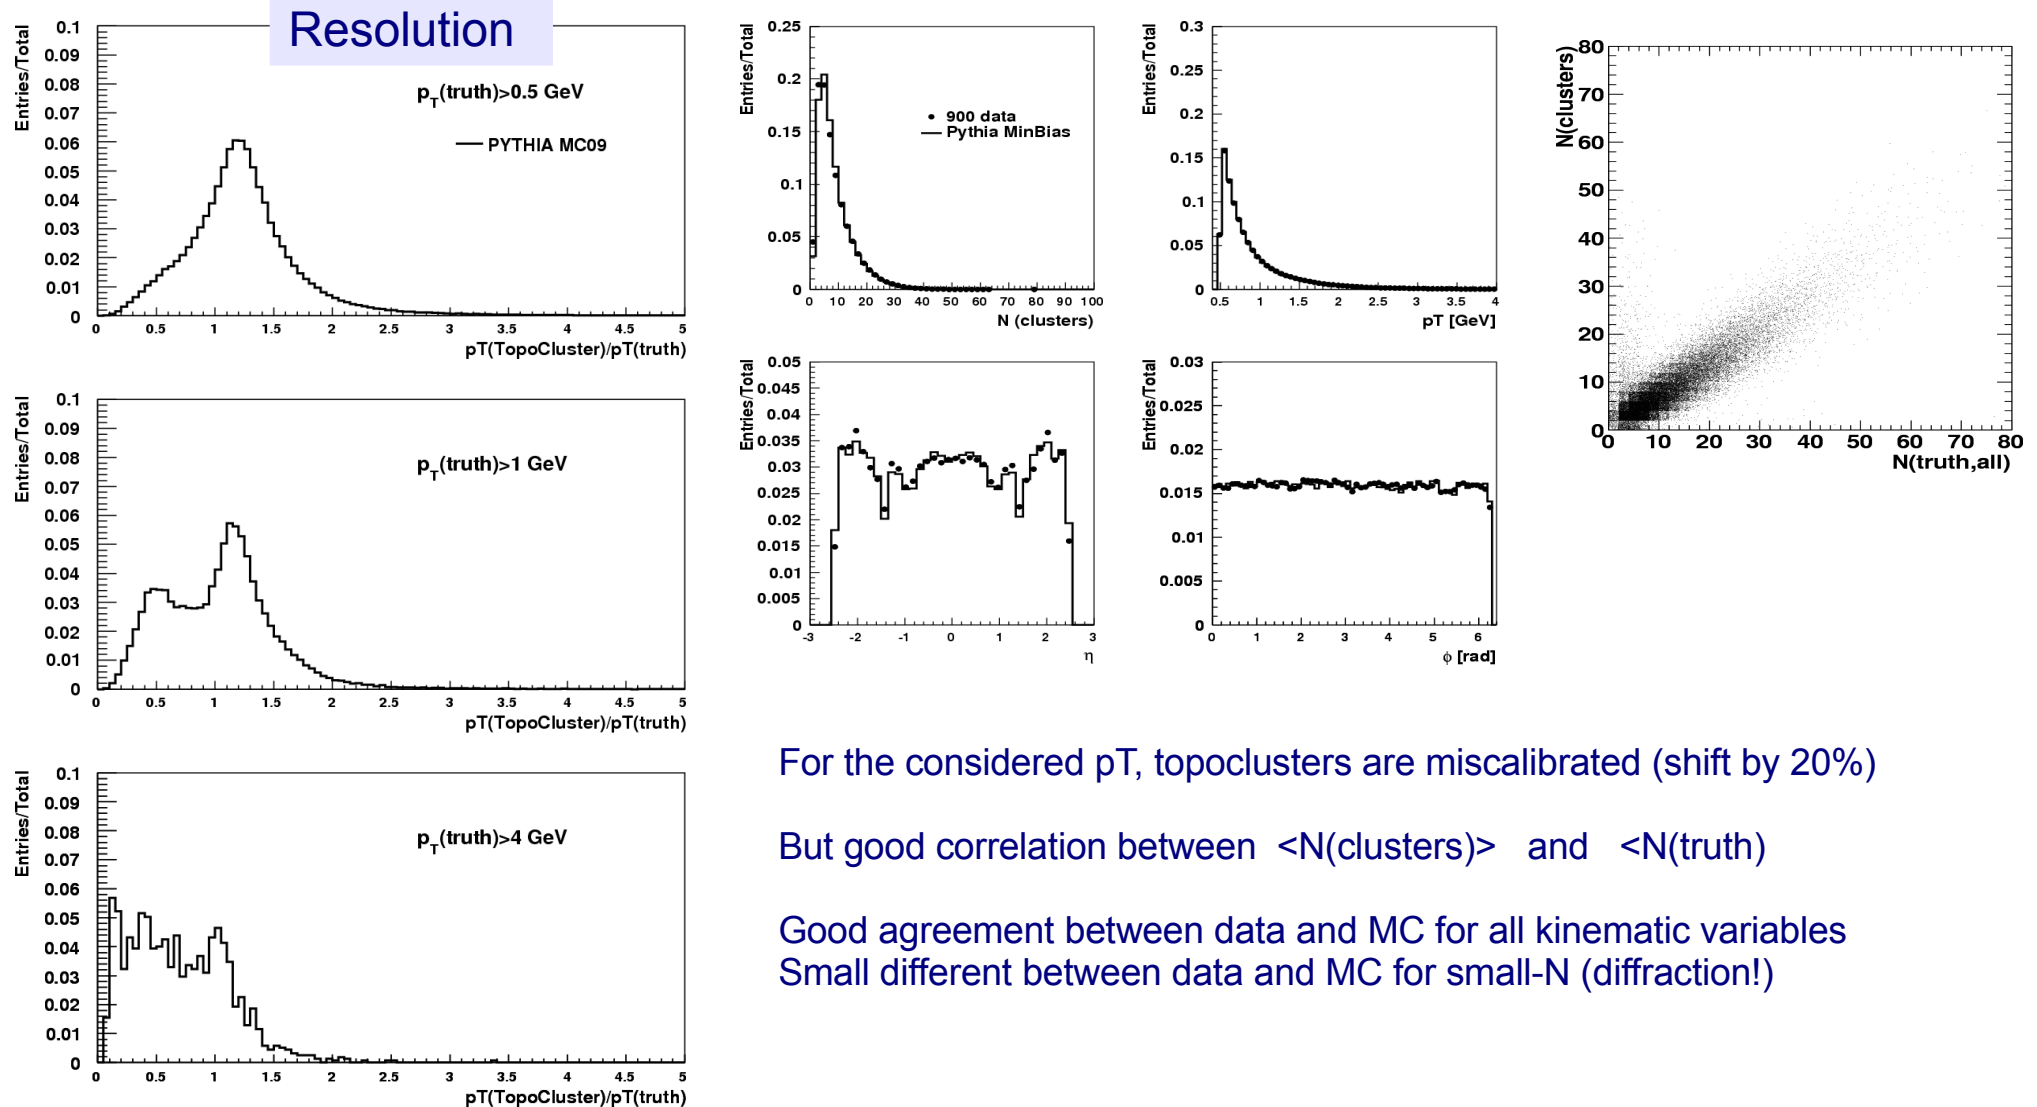

## *Plan of this talk*

- ◆ Discuss TopoClusters after calibration.
- ◆ Reconstruct detector-level distributions, correction factors, unfolded distributions
- ◆ What measurements can be considered?
  - Must be **sensitive to the physics we are interested in** (i.e. UE)
  - Must be **instrumentally well measured**
    - ◆ Small bin-by-bin correction factors:  $C = N(\text{gen})/N(\text{reco}) = \text{purity} / \text{efficiency}$
    - ◆ Means small instrumental systematics
      - ◆ Small sensitivity to miscalibration, cut threshold effects, energy scale etc.
- ◆ Look at the EM-scale. Can the EM-scale TopoClusters change the conclusion
- ◆ Use the central region  $|\eta| < 2.5$ 
  - easier to control the scale, possible cross check with tracks
  - under pressure of moving towards 7 TeV data..

# TopoClusters at calibrated scale

Look at **Calibrated TopoClusters**. Use MC09 MinBias PYTHIA vs 900 GeV data

For the considered  $p_T$ , topoclusters are miscalibrated (shift by 20%)

But good correlation between  $\langle N(\text{clusters}) \rangle$  and  $\langle N(\text{truth}) \rangle$

Good agreement between data and MC for all kinematic variables  
Small different between data and MC for small- $N$  (diffraction!)

# $\delta\phi$ measurements: average $p_T$

detector-level

after correction

bin-by-bin corrections

- ◆ “birth” of the leading jet (at  $\delta\phi=0$ ) and second leading jet ( $\delta\phi=-\pi,\pi$ ) with increase of  $p_T$
- ◆ Shows “average size” of leading ( $\delta\phi=0$ ) and second leading jet
- ◆ Perugia0 tune is significantly below the data
- ◆ Unlike previous measurement, **correction factors are small**.

# $\delta\phi$ measurements: particle densities

detector-level

after correction

bin-by-bin corrections

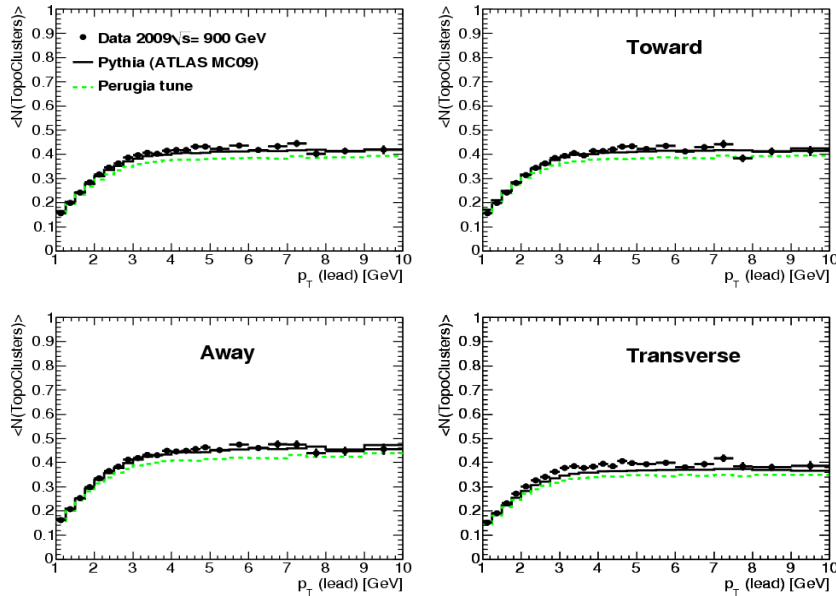

- ◆ “birth” of the leading jet (at  $\delta\phi=0$ ) and second leading jet ( $\delta\phi=-\pi,\pi$ ) with increase of  $p_T$
- ◆ Shows “average size” of leading ( $\delta\phi=0$ ) and second leading jet
- ◆ Differences with Pythia MinBias in shapes and normalization
- ◆ Correction factors are not small, but the same difference between data and MC is already present at the detector levels. Similar conclusion is obtained for average- $p_T$  flow (also similar correction factor)

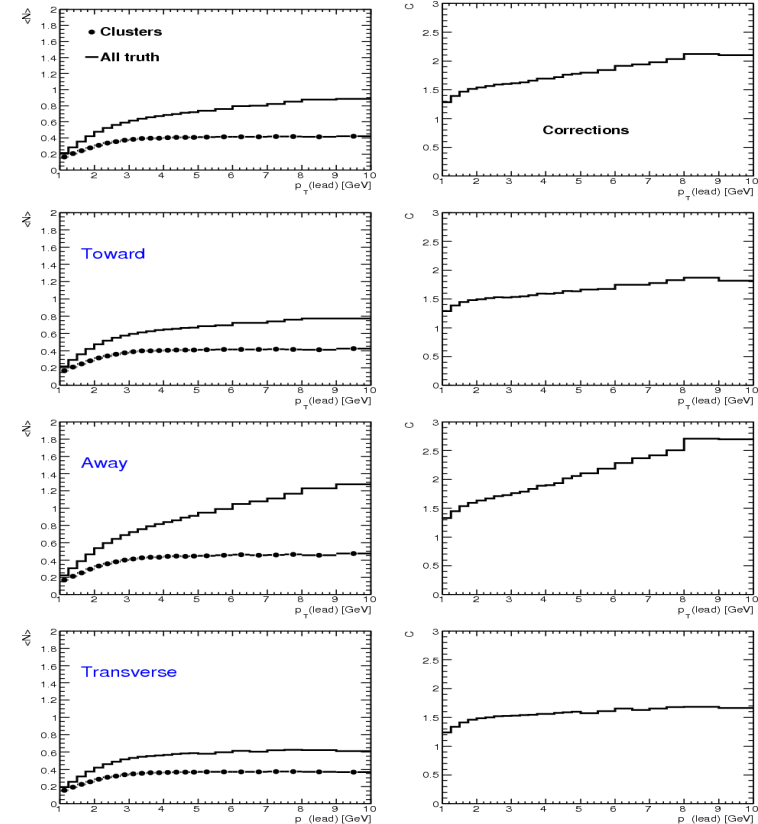

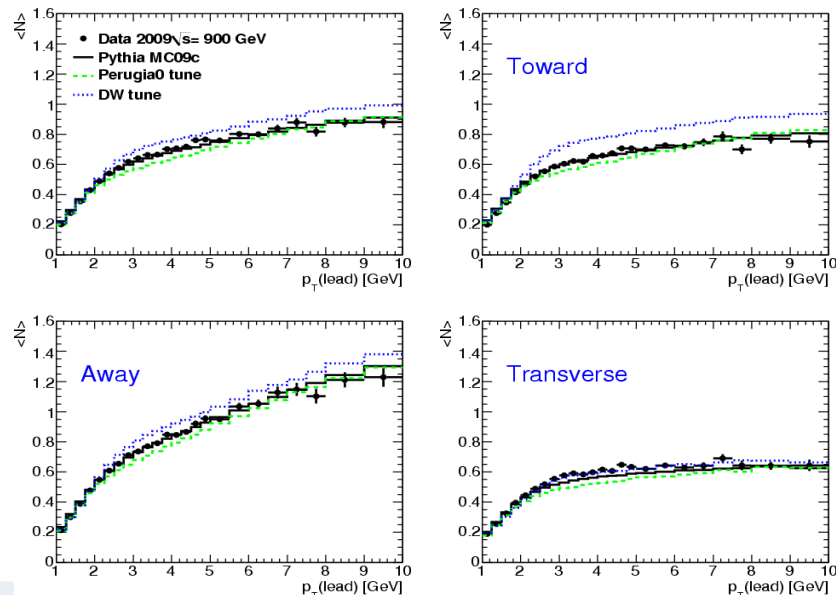

# Densities as a function of $p_T(\text{lead})$

detector-level

bin-by-bin corrections

after correction

- corrections are rather large at large  $p_T(\text{lead})$

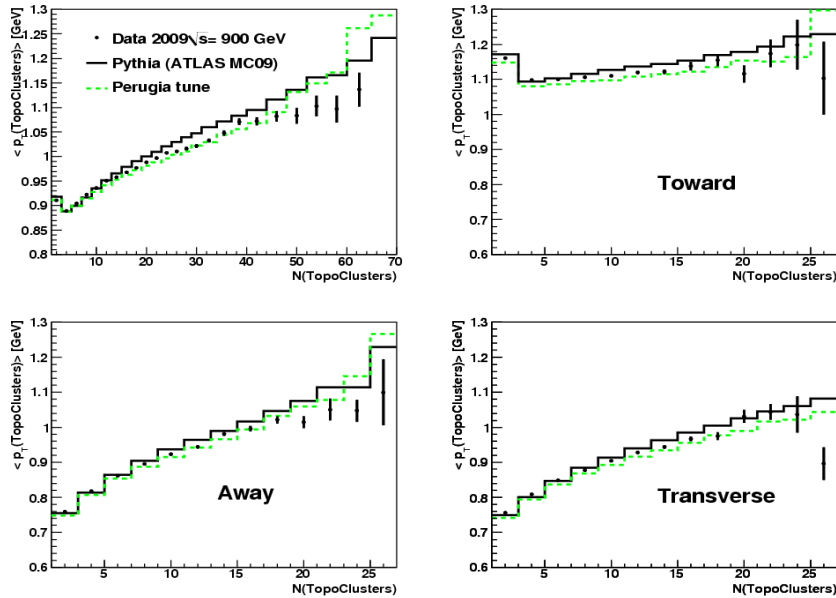

- rise as a function of  $p_T(\text{lead})$  is driven by corrections (picking lead TopoCluster does not mean going to harder scale due to the resolution effects)

- but difference between data and MC remains the same after correction. We do not lose this information by applying the bin-by-bin corrections!

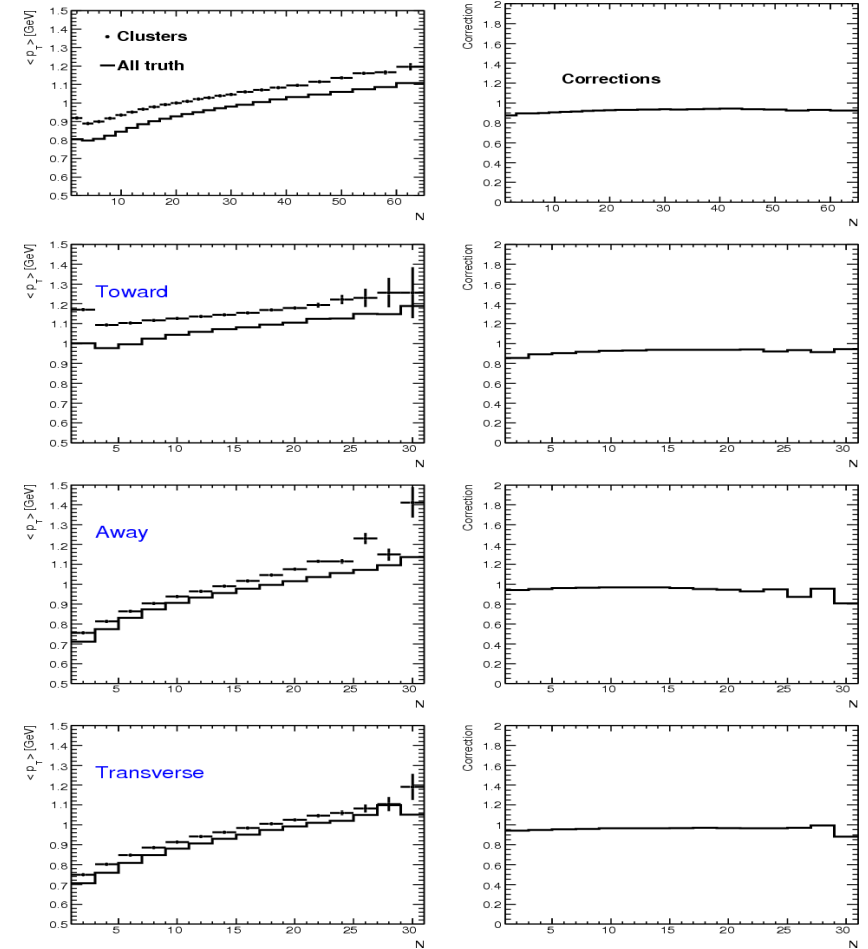

# Average $p_T$ as a function of multiplicities

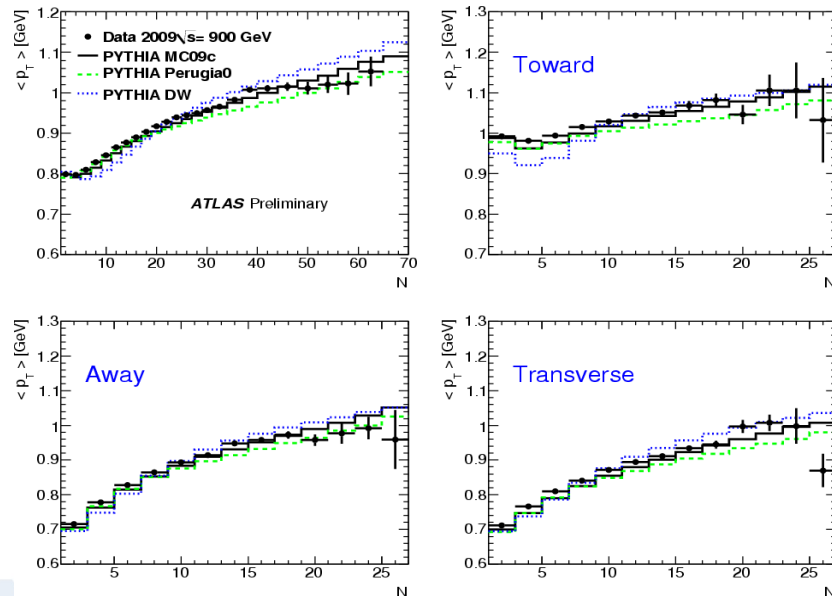

## detector-level

## bin-by-bin corrections

## after correction

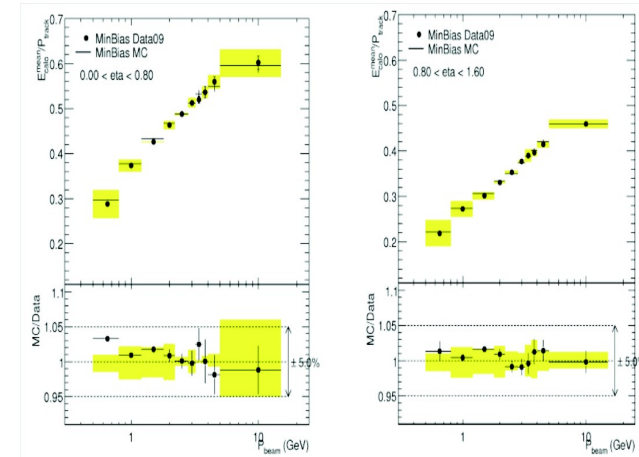

Corrections are small ( $\sim 1$ )

Inefficiency affects both X and Y axes.

# Systematic uncertainties

- ◆ Reject events with  $N(\text{clusters}) < 3$  (diffraction)
- ◆  $\pm 5\%$  energy scale
- ◆ 10 MeV electronic nose shift in MC
- ◆  $\pm 0.025$  rad for cluster centers  $\phi$  and  $\eta$  (one-cell shift)
- ◆ +10% extra material.
- ◆ Using Peruji0 for unfolding
- ◆ Repeat the analysis using EM-scale clusters
- ◆ Working on the  $\pi^0$  peak to understand systematics

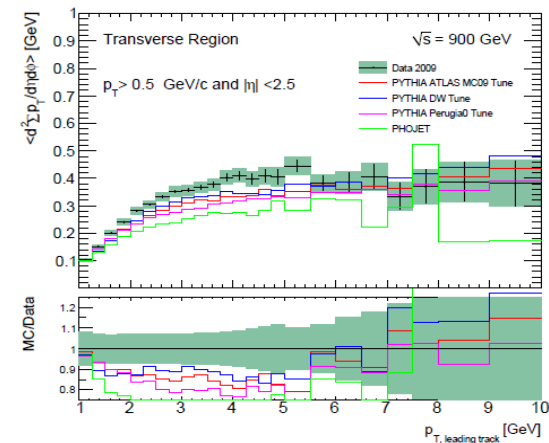

# Figures with systematics included

# Results are similar as in the UE/MinBias tracking notes

ATL-COM-PHYS-2010-165

ATL-COM-PHYS-2010-164

# Summary

- ◆ **Studies based on TopoClusters confirm the conclusions for charged-particle UE studies.**
  - MC tunes have smaller particle activity in the transverse regions
  - Monte Carlo tunes disagree with data
    - ✓ the largest problem with Perugia0 and DW tunes
- ◆ **Provide an independent check of track-based measurements**
- ◆ **Not every distribution done using tracks can be repeated using TopoClusters due to resolution and overlap effects**
- ◆ **We will concentrate on the distributions which have small bin-by-bin corrections using calibrated TopoClusters**
  - $\langle p_T \rangle$  vs  $N$  and  $\langle p_T \rangle$  as function  $\delta\phi$  have detector correction  $\sim 1$
- ◆ **Finish the draft note and move forward with 7 TeV data**
  - **Convert 7 TeV D3PD (or ESD, AOD) to ntuples suitable for analysis**
    - ✓ Smaller size, fast turnover, faster systematics checks
